FlashAttention-2: Faster Attention with Better Parallelism and Work Partitioning

Tri Dao

FlashAttention: Fast and Memory-Efficient Exact Attention with IO-Awareness

Tri Dao, Daniel Y. Fu, Stefano Ermon, Atri Rudra, and Christopher Ré
GPU Memory Hierarchy

- A massive number of threads to execute an operation (kernel)
  - Load input from HBM to registers and SRAM
  - Computes
  - Load output to HBM
Attention is the Heart of Transformers

\[ O = \text{Dropout}(\text{Softmax}(\text{Mask}(QK^T)))V \]

\[ S = QK^T \in \mathbb{R}^{N \times N}, \quad P = \text{softmax}(S) \in \mathbb{R}^{N \times N}, \quad O = PV \in \mathbb{R}^{N \times d}, \]

**Algorithm 0 Standard Attention Implementation**

**Require:** Matrices \( Q, K, V \in \mathbb{R}^{N \times d} \) in HBM.

1. Load \( Q, K \) by blocks from HBM, compute \( S = QK^T \), write \( S \) to HBM.
2. Read \( S \) from HBM, compute \( P = \text{softmax}(S) \), write \( P \) to HBM.
3. Load \( P \) and \( V \) by blocks from HBM, compute \( O = PV \), write \( O \) to HBM.
4. Return \( O \).
Approximate Attention

FlashAttention is Exact Attention
FlashAttention

\[ O = \text{Dropout}(\text{Softmax}(\text{Mask}(QK^T)))V \]

Challenge
- softmax normalization has row dependency
- Attention Matrix has quadratic memory consumption to the seq length

Purpose
- Compute softmax normalization without access to full input
- Backward without the large attention matrix from forward

Approach
- Tiling: Restructure algorithm to load block by block from HBM to SRAM
- Recomputation: Don’t store attn. matrix from forward, but recompute
Online softmax instead computes “local” softmax with respect to each block and rescale to get the right output at the end.

Maxim Milakov and Natalia Gimelshein. Online normalizer calculation for softmax.
Recomputation

By storing softmax normalization factors from forward, quickly recompute attention in the backward from input in SRAM

FlashAttention is still not as efficient as other primitives (GEMM).

Modern GPUs have specialized compute units (e.g., Tensor Cores on Nvidia GPUs) that makes matmul much faster.

Non-matmul FLOP is $16\times$ more expensive than a matmul FLOP.

- The forward pass only reaches 30-50% of the maximum throughput.
- The backward pass only reaches 25-35% of maximum throughput.

Optimized GEMM can reach up to 80-90% of the theoretical maximum device throughput.
FlashAttention2

1. **Algorithm**: Tweak the algorithm from FlashAttention to reduce the number of non-matmul FLOPs.

2. **Parallelism**: Additionally parallelize over the sequence length

3. **Work Partitioning**: Decide how to partition the work between different warps.
Algorithm

\[ m^{(1)} = \text{rowmax}(S^{(1)}) \in \mathbb{R}^B, \]
\[ \ell^{(1)} = \text{rowsum}(e^{S^{(1)} - m^{(1)}}) \in \mathbb{R}^B, \]
\[ \tilde{p}^{(1)} = \text{diag}(\ell^{(1)})^{-1} e^{S^{(1)} - m^{(1)}} \in \mathbb{R}^{B \times B}, \]
\[ O^{(1)} = \tilde{p}^{(1)} V^{(1)} = \text{diag}(\ell^{(1)}^{-1}) e^{S^{(1)} - m^{(1)}} V^{(1)} \in \mathbb{R}^{B \times d}, \]
\[ m^{(2)} = \max(m^{(1)}, \text{rowmax}(S^{(2)})) = m \]
\[ \ell^{(2)} = e^{m^{(1)} - m^{(2)}} \ell^{(1)} + \text{rowsum}(e^{S^{(2)} - m^{(2)}}) = \text{rowsum}(e^{S^{(1)} - m}) + \text{rowsum}(e^{S^{(2)} - m}) = \ell \]
\[ \tilde{p}^{(2)} = \text{diag}(\ell^{(2)})^{-1} e^{S^{(2)} - m^{(2)}} \]
\[ O^{(2)} = \text{diag}(\ell^{(1)})^{-1} \ell^{(2)} \tilde{p}^{(2)} V^{(2)} = \text{diag}(\ell^{(2)})^{-1} e^{S^{(2)} - m} V^{(2)} + \text{diag}(\ell^{(2)})^{-1} e^{S^{(2)} - m} V^{(2)} = O. \]

**FlashAttention2**

\[ m^{(1)} = \text{rowmax}(S^{(1)}) \in \mathbb{R}^B, \]
\[ \ell^{(1)} = \text{rowsum}(e^{S^{(1)} - m^{(1)}}) \in \mathbb{R}^B, \]
\[ O^{(1)} = e^{S^{(1)} - m^{(1)}} V^{(1)} \in \mathbb{R}^{B \times d}, \]
\[ m^{(2)} = \max(m^{(1)}, \text{rowmax}(S^{(2)})) = m \]
\[ \ell^{(2)} = e^{m^{(1)} - m^{(2)}} \ell^{(1)} + \text{rowsum}(e^{S^{(2)} - m^{(2)}}) = \text{rowsum}(e^{S^{(1)} - m}) + \text{rowsum}(e^{S^{(2)} - m}) = \ell \]
\[ \tilde{p}^{(2)} = \text{diag}(\ell^{(2)})^{-1} e^{S^{(2)} - m^{(2)}} \]
\[ O^{(2)} = \text{diag}(\ell^{(1)})^{-1} \ell^{(2)} \tilde{p}^{(2)} V^{(2)} = e^{S^{(1)} - m} V^{(1)} + e^{S^{(2)} - m} V^{(2)} \]
\[ O^{(2)} = \text{diag}(\ell^{(2)})^{-1} \tilde{O}^{(2)} = O. \]
Parallelism

- FlashAttention parallelizes over batch size and number of head
- There are BS * #head thread blocks, each running on a Streaming multiprocessor (SM)
- A100 -- 108 SMs

Parallelize over batch size and number of head → Parallelize over the b. h. and seq length dimension

- FlashAttention
  - For j-th (K, V), for i-th Q, compute using Kj, Vj, Qi in SRAM, and update Oi, li, mi in HBM
- FlashAttention2
  - Swap order of loop
  - Parallelize outer loop
  - Leads to improved occupancy

Forward pass

Worker 1
Worker 2
Worker 3
Worker 4
Worker 5

White square: causal mask for cases like auto-regressive language modeling
Work Partitioning Between Warps

We typically use 4 or 8 warps per thread block
- FlashAttention
  - Split K and V
  - All warps need to write intermediate results out to shared memory, synchronize, then add up
- FlashAttention2
  - Split Q
  - No need for communication between warps

2.8X faster than baseline
1.3X faster than FlashAttention
Summary

• FlashAttention2 is 2x faster than FlashAttention
• FlashAttention2 will also speed up training, finetuning, and inference

• Future Directions
  • Device dependent, only applicable to Nvidia A100
  • Hand-writing CUDA implementation, specially designed for specific attention implementation
  • How the FlashAttention2 performs on sparse attention mechanisms
  • Auto-tuning mechanisms for selecting optimal block sizes and partitioning strategies could simplify the use of FlashAttention-2
